### Content

#### Materials and Methods

**Table S1.** Sequences of all primers used in the present study.

**Figure S1.** Multiple sequence alignments of KAS-II enzymes.

**Figure S2.** CDA plate bioassays of MT1110 wt and *fabF3* mutant strains.

**Figure S3.** LC-MS analysis of CDAs from MT1110 and the mutant strain (Phe107Ile)

**Figure S4.** UV spectra of ebCDA4a and bCDA4a.

**Figure S5.** High resolution LC-MS and MS-MS of ebCDA4a.

**Figure S6.** High resolution LC-MS and MS-MS of bCDA4a.

**Figure S7.** Bioassay of purified bCDA4a/ebCDA4a vs. CDA4a.

## Materials and Methods

**Bacterial strains, microbiological methods and genetic manipulations.** The *Streptomyces coelicolor* A(2) strain, MT1110 which is a SCP1<sup>-</sup>, SCP2<sup>-</sup> derivative of the wt strain 1147 was used [S1]. All methods used for growth and transformation of *E. coli* and *S. coelicolor* are as described previously [S1, S2]. A 2kb DNA fragment spanning *fabF3* was amplified by PCR using *S. coelicolor* MT1110 genomic DNA as template and primers fabF3Up and fabF3Down (Table 1). The PCR product was digested with *Xba*I (Roche) and cloned into similarly cut pHSG398 [8], treated with Antarctic phosphatase (NEB), to yield pRAL75. This construct was used in the QuikChange protocol (Stratagene) using a series of mutagenic primer pairs (Table 1) designed to substitute Ile (FabF3IleUp & fabF3IleDown), Leu (FabF3LeuUp & fabF3LeuDown) and Ala (FabF3AlaUp & fabF3AlaDown) residues for Phe108. The mutagenized codons were selected according to *S. coelicolor* codon usage preference. The presence of the desired mutations was verified by DNA sequencing (MWG) using forward and reverse universal M13 primers, and the mutated inserts were each cloned into the *S. coelicolor* suicide vector pMAH as *Xba*I fragments to generate the deletion constructs pRAL7591 (F-I), pRAL7592 (F-L) and pRAL7593 (F-A) respectively. After passaging through the DNA demethylating *E. coli* strain ET12567 these constructs were used to transform *S. coelicolor* MT1110 protoplasts and transformants were selected for using hygromycin. Following two rounds of unselective growth hygromycin sensitive colonies, identified by replica plating, were screened, using DNA sequencing (MWG) of PCR products generated using primers fabf3M13foward & faBf3M13reverse (Table 1) spanning the mutated region of *fabF3*, to identify mutants. CDA plate bioassays were effected as described previously [S3] using standardized numbers of spores ( $5 \times 10^7$ ).

**Cultivation of *S. coelicolor*, Isolation and Detection of CDA variants.** Wild-type MT1110 and mutant strains *fabF3* F-I, F-L, F-S were grown on solid MS media, then inoculated into SV2 liquid media [S2] and incubated for a further 5 days at 28°C and 180 rpm. Liquid media was spun down at 4500 rpm for 10 minutes; the supernatant was filtered, adjusted to pH 2.0 with 1M HCl and then re-filtered before being loaded onto a Varian C-18 Bond Elute SPE cartridge. Crude CDA was extracted using a methanol gradient (30-100%), evaporated under reduced pressure and analysed using LC-MS [4].

**Purification of CDA variants.** CDA extracts were purified on a Varian Prostar instrument, equipped with a Prostar 335 photodiode array detector. Purification was achieved using semipreparative reversed phase HPLC: Phenomenex C-18 5mm, 250 × 10 mm column. Solvent A was H<sub>2</sub>O containing 0.1% HCO<sub>2</sub>H and solvent B was acetonitrile containing 0.1% HCO<sub>2</sub>H. At a flow rate of 3 mL min<sup>-1</sup> B was increased from 5% to 100% over a 30 min linear gradient, held at 100% for 5 min before being brought back down to 5% (pre-equilibration for next run); detection by UV at 280 nm and 350 nm. Fractions were analysed by LC-MS [4].

**Analysis of CDA Extracts Using LC-MS.** General LC-MS analysis was carried out on a Micromass LCT orthogonal acceleration time of flight mass spectrometer, equipped with an electrospray ionisation source run in positive mode (scanning from 700 to 1700 *m/z*) combined with a Waters 2790 Separation module. A reversed phase C-18 150 x 4.6 mm 3 μm Phenomenex column was used. Solvent A was H<sub>2</sub>O with 1 % acetonitrile and 0.1 % HCO<sub>2</sub>H and solvent B was acetonitrile with 1 % H<sub>2</sub>O and 0.1 % HCO<sub>2</sub>H. At a flow rate of 1 ml min<sup>-1</sup> with a gradient of 80 % A and 20 % B, increasing to 70 % B over 10 min and increased to 100 % B over the 1 min and held for a further 4 min.

#### **Accurate Mass and Tandem MS analyses of CDA using LTQ-Orbitrap XL- nUPLC**

Samples were initially diluted in water, and subsequently in 95 % water/ 5 % acetonitrile supplemented with 0.1 % HCO<sub>2</sub>H (hereafter referred to as Buffer A1). Data were acquired using a nanoacquity chromatograph (Waters MS technologies) coupled to an LTQ-Orbitrap XL mass spectrometer (ThermoFisher Scientific) equipped with the manufacturer's dynamic nanospray source, fitted with a PicoTip emitter (20-10 μm diameter, New Objective). The sample temperature in the autosampler was maintained at 10 °C, and 4 μl of sample was injected initially onto a trapping column (Waters C-18 180 μm × 20 mm), with a sample loading time of 1 min, using the partial loop mode of injection, at a flow rate of 18 μl/min (Buffer A1). Following loading, the valve position was switched, such that the trapping and analytical columns were in-line with respect to each other, and on-line with the mass spectrometer. The analytical column (nanoACQUITY UPLC™ BEH C-18 75 μm × 150 mm 1.7 μm column) was maintained at a temperature of 35 °C, and at a constant flow rate of 300 nl/min. The gradient conditions were as follows: 0.33 min – 5 % acetonitrile/0.1 % HCO<sub>2</sub>H,

up to 50 % acetonitrile/ 0.1 % HCO<sub>2</sub>H over a 30 min linear gradient; 31 min – 85 % acetonitrile/ 0.1 % HCO<sub>2</sub>H, 35 min, 5 % acetonitrile/ 0.1 % HCO<sub>2</sub>H (pre-equilibration for the next run). The total length of an analytical run was 50 min.

For high mass accuracy, all spectra were acquired in an LTQ-Orbitrap XL with the Orbitrap operating at a resolution of 30,000 (defined at m/z 400). The Orbitrap was set to acquire alternate full MS scans, and tandem MS data from the linear ion trap. Data were acquired in positive ion mode using Xcalibur version 2.0.5 and Tuneplus version 2.4 SP1, and in data-dependent mode, with the most intense peak from full MS spectra directing collision induced dissociation (CID), at normalized collision energy of 35 %, and an activation q of 0.25. Dynamic exclusion was applied for a duration of 30 sec, with a repeat count of 2, and an exclude duration width of 180 sec to avoid repeated selection of the same m/z precursors for MSMS.
